August 2026

Submission Documentation

The Weather-Bot 3000 is a simple Python program that demonstrates input handling, validation, type conversion, Boolean logic, and conditional control flow. The program first asks the user to enter the current temperature in Celsius. Before converting the input to an integer, it uses `isdigit()` to check whether the entered value contains valid digits. Based on the temperature, the program provides one of three recommendations: turn on the AC for hot weather, carry a jacket for chilly weather, or enjoy the day when the temperature is optimal. The program also asks whether it is raining and uses a membership test with `lower()` to provide an umbrella recommendation. This program demonstrates the input–validate–decide pattern using both numeric and string conditions.

Python Source Code

```
"""
Program : Weather-Bot 3000
Purpose : Gives simple lifestyle advice based on temperature and rain
Author : Punit Kumar
Date : 08 August 2026
"""

print("Welcome to your AI Climate Assistant.")

temp_input = input(
    "What is the current temperature in Celsius?: "
).strip()

if temp_input.isdigit():
    temperature = int(temp_input)
```

```

if temperature > 30:
    print("AI Alert: It's hot! AI suggests turning on the AC.")

elif temperature < 15:
    print("AI Alert: Chilly! AI suggests a jacket.")

else:
    print("AI Analysis: Temperature is optimal. Enjoy your day!")

rain_check = input(
    "Is it raining outside? (yes/no): "
)

if "yes" in rain_check.lower() and temperature < 15:
    print(
        "AI Recommendation: Stay indoors today, "
        "and carry an umbrella."
    )

elif "yes" in rain_check.lower():
    print("AI Recommendation: Carry an umbrella.")

else:
    print("AI Recommendation: No umbrella needed.")

else:
    print(
        "Please enter the temperature as a valid number "
        "(digits only)."
    )

```

Program Output

The program accepts the temperature as input and validates it before performing numerical comparisons.

```

Welcome to your AI Climate Assistant.
What is the current temperature in Celsius?: 35
AI Alert: It's hot! AI suggests turning on the AC.
Is it raining outside? (yes/no): no
AI Recommendation: No umbrella needed.

```

```
Welcome to your AI Climate Assistant.  
What is the current temperature in Celsius?: 10  
AI Alert: Chilly! AI suggests a jacket.  
Is it raining outside? (yes/no): yes  
AI Recommendation: Stay indoors today, and carry an umbrella.
```

```
Welcome to your AI Climate Assistant.  
What is the current temperature in Celsius?: 25  
AI Analysis: Temperature is optimal. Enjoy your day!  
Is it raining outside? (yes/no): yes  
AI Recommendation: Carry an umbrella.
```

Conclusion

The Weather-Bot 3000 successfully demonstrates the use of input validation, integer conversion, comparison operators, Boolean logic, and `if/elif/else` conditional statements. The program also combines numerical temperature conditions with string-based rain conditions to produce simple recommendations. It provides a small example of how a Python program can accept input, validate it, make decisions, and generate an appropriate response.
